

HOUSING PRICE PREDICTION

Submitted by:

VIVEK ANAND

INTRODUCTION

Business Problem Framing

Houses are one of the necessary needs of each and every person around the globe and therefore housing and real estate market is one of the markets which is one of the major contributors in the world's economy. It is a very large market and there are various companies working in the domain. Data science comes as a very important tool to solve problems in the domain to help the companies increase their overall revenue, profits, improving their marketing strategies and focusing on changing trends in house sales and purchases. Predictive modeling, Market mix modeling, recommendation systems are some of the machine learning techniques used for achieving the business goals for housing companies. Our problem is related to one such housing company

A US-based housing company named Surprise Housing has decided to enter the Australian market. The company uses data analytics to purchase houses at a price below their actual values and flip them at a higher price. For the same purpose, the company has collected a data set from the sale of houses in Australia. The data is provided in the CSV file below.

The company is looking at prospective properties to buy houses to enter the market. It is required to build a model using Machine Learning in order to predict the actual value of the prospective properties and decide whether to invest in them or not. So we are building a model that helps to determine which variables are important to predict the price of variables & also how do these variables describe the price of the house.

This model will help to determine the price of houses with the available independent variables. This model will then be used by the management to understand how exactly the prices vary with the variables. They can accordingly manipulate the strategy of the firm and concentrate on areas that will yield high returns. Further, the model will be a good way for the management to understand the pricing dynamics of a new market.

Conceptual Background of the Domain Problem

As we are working on the Housing project dataset we can easily understand that the data belongs to the Housing and Real Estate which will eventually involve several Financial, Costing, Area & Neighborhood, Statistical, and Technical terms in the dataset. As this data belongs to a US-based housing company named Surprise Housing as they have decided to enter the Australian market. The company uses data analytics to purchase houses at a price below their actual values and flip them at a higher price. So here we need to understand several words related to the core Domain.

The domain related concepts which are useful for better understanding of the project are. Some relevant details of individual columns are,

1. MSSubClass: Identifies the type of dwelling involved in the sale.

20 1-STORY 1946 & NEWER ALL STYLES

30 1-STORIES 1945 & OLDER

40 1-STORY W/FINISHED ATTIC ALL AGES

45 1-1/2 STORY - UNFINISHED ALL AGES

50 1-1/2 STORY FINISHED ALL AGES

60 2-STORIES 1946 & NEWER

70 2-STORIES 1945 & OLDER

75 2-1/2 STORY ALL AGES

80 SPLIT OR MULTI-LEVEL

85 SPLIT FOYERS

90 DUPLEX - ALL STYLES AND AGES

120 1-STORY PUD (Planned Unit Development) - 1946 & NEWER

78. SaleCondition: Condition of sale

Normal Normal Sale

Abnorml Abnormal Sale - trade, foreclosure, short sale

AdjLand Adjoining Land Purchase

Alloca Allocation - two linked properties with separate deeds, typically condo with a garage unit

Family Sale between family members

Partial Home was not completed when last assessed (associated with New Homes)

Review of Literature

This section discusses about the reported work carried out in various fields of Housing project & Real Estate sectors.

Chris Herbert et. Al., describes that household growth is now back from post-recession lows, but new home construction remains depressed, with additions to supply barely keeping pace with the number of new households. The most significant factors, however, are raising land prices and regulatory constraints on development. [Interactive Map] These constraints, largely imposed at the local level, raise costs and limit the number of homes that can be built in places where demand is highest. Meanwhile, a large percentage of new housing being built is intended primarily for the higher end of the market. The limited supply of smaller, more affordable homes in the face of rising demand suggests that the rising land costs and the difficult development environment make it unprofitable to build for the middle market. Also the number of homeowners rose sharply, even as the ratio of median home price to median household income rose from a low of 3.3 in 2011 to 4.1 in 2018, a sign of deteriorating affordability.

Gordon Davis et. Al., describes that housing affordability is an economic and social problem that affects rich and poor countries alike. No respecter of nationalities or cultures, it arises whenever fewer units of housing are available for sale or rent, for whatever reasons - in a given price or rent range than the number of households looking to buy or rent that can afford housing at the given price or rent. In fact, housing affordability problems tend to migrate down the price/rent scale. Regardless of the price range where a housing shortage first arises, buyers

in that price range will tend to bid up less expensive units, the end result being to drive the shortage to the lower end of the housing price range. The rental market functions the same way: a shortage in supply of rental units in any rent range will migrate to the lower end. And, as alluded to above, as between purchases and rentals, rising purchase prices tend to nudge rents higher, and vice versa. The factors influencing the availability of affordable housing might be viewed as falling into two categories: market factors and individual household factors.

Nehal N Ghosalkar et. Al., describes that the real estate market is a standout amongst the most focused regarding pricing and keeps fluctuating. It is one of the prime fields to apply the ideas of machine learning on how to enhance and foresee the costs with high accuracy. There are three factors that influence the price of a house which includes physical conditions, concepts and location. The current framework includes estimating the price of houses without any expectations of market prices and cost increment. The objective of the paper is prediction of residential prices for the customers considering their financial plans and needs. By breaking down past market patterns and value ranges, and coming advancements future costs will be anticipated. This examination means to predict house prices in the city with Linear Regression. It will help clients to put resources into a bequest without moving toward a broker.

Elena Sliogeris et. Al., describes that incidence of the problem has spread from very low-income through low-income into moderate-income households. There is now a consistent call for housing schemes to retain 'key workers' and 'the working poor' in established areas to ensure access to employment, education, public transport and other facilities and amenities. Land com has a strategic position within this landscape and there exists a range of current and potential mechanisms land com might utilise to create and maintain a pool of affordable houses. Numerous interrelated factors have driven the loss of affordability, including an increased willingness and capacity to pay for housing due to increased incomes and more accessible lines of credit. Concurrent increases in population, decreases in household size and increases in house size have further compounded the problem. The role of supply-side impediments to housing development that contribute to a loss of affordability is strongly contested. The

planning processes may have a role to play in addressing affordability concerns. However, the house prices are largely countered by recent market conditions in city areas have continued to increase in price while house prices in outer areas have stagnated or decreased in value. The landscape of affordability is influenced to a large extent by access to jobs, public transport and other social amenities. This highlights the need for future housing provision to address employment, transport and other infrastructure as well as the volume of housing supply.

George Earl et. Al., describes that markets are the central institutions of economies, allowing people to buy and sell goods and services in a manner that potentially makes everyone better off. However, markets can only be formed under certain conditions, and when these conditions are absent, markets may struggle to exist or the conditions may lead to market failures. This is the basic underlying principle of missing or incomplete markets; that is, failure to produce some goods and services despite being needed or wanted. It is well known that microeconomic equilibrium occurs when the demand for goods is equal to the supply. A missing market, therefore, is a sign that the market is out of equilibrium; a situation where markets do not exist or where the equilibrium price is not related to either marginal social benefits or marginal social costs. For decades, the market has been failing to meet the housing needs of its lowest income residents, and the situation is getting steadily worse. Many people on low incomes cannot afford to buy their own homes, and housing rents have also become increasingly unaffordable in recent years. Therefore, by definition, sustainable housing means that everyone should have the opportunity to live in a decent home at a price they can afford, in a place in which they want to live and work.

Analytical Problem Framing

Mathematical/ Analytical Modeling of the Problem

We are building a model Machine Learning in order to predict the actual value of the prospective properties and decide whether to invest in them or not. So this model will help us to determine which variables are important to predict the price of variables & also how do these variables describe the price of the house. This

will help to determine the price of houses with the available independent variables. They can accordingly manipulate the strategy of the firm and concentrate on areas that will yield high returns.

Regression analysis is a set of statistical processes for estimating the relationships between a dependent variable (often called the 'outcome variable') and one or more independent variables (often called 'predictors', 'covariates', or 'features'). The most common form of regression analysis is linear regression, in which one finds the line (or a more complex linear combination) that most closely fits the data according to a specific mathematical criterion. For specific mathematical reasons this allows the researcher to estimate the conditional expectation of the dependent variable when the independent variables take on a given set of values.

Regression analysis is a form of predictive modelling technique which investigates the relationship between a dependent (target) and independent variable (predictor). This technique is used for forecasting, time series modelling and finding the causal effect relationship between the variables

The different Mathematical/Analytical models that are used in this project are as below.

1. **Linear regression** - is a linear model, e.g. a model that assumes a linear relationship between the input variables (x) and the single output variable (y). More specifically, that y can be calculated from a linear combination of the input variables (x).
2. **Lasso** - In statistics and machine learning, lasso is a regression analysis method that performs both variable selection and regularization in order to enhance the prediction accuracy and interpretability of the resulting statistical model.
3. **Ridge** - regression is a way to create a parsimonious model when the number of predictor variables in a set exceeds the number of observations, or when a data set has multi co linearity (correlations between predictor variables).
4. **Elastic Net** - is a popular type of regularized linear regression that combines two popular penalties, specifically the L1 and L2 penalty functions. Elastic

net linear regression uses the penalties from both the lasso and ridge techniques to regularize regression models. The technique combines both the lasso and ridge regression methods by learning from their shortcomings to improve on the regularization of statistical models.

5. **K Neighbors Regressor** - KNN algorithm can be used for both classification and regression problems. The KNN algorithm uses 'feature similarity' to predict the values of any new data points. This means that the new point is assigned a value based on how closely it resembles the points in the training set.
6. **Decision Tree** - is one of the most commonly used, practical approaches for supervised learning. It can be used to solve both Regression and Classification tasks with the latter being put more into practical application. It is a tree-structured classifier with three types of nodes.
7. **Random forest** - is a meta estimator that fits a number of classifying decision trees on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. A Random Forest's nonlinear nature can give it a leg up over linear algorithms, making it a great option.
8. **AdaBoost Regressor** - is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.
9. **GradientBoosting Regressor** - GB builds an additive model in a forward stage-wise fashion; it allows for the optimization of arbitrary differentiable loss functions. In each stage a regression tree is fit on the negative gradient of the given loss function.
10. **XGBoost Regressor** - XGBoost is an implementation of gradient boosted decision trees designed for speed and performance

Data Pre-processing

Data pre-processing in Machine Learning refers to the technique of preparing (cleaning and organizing) the raw data to make it suitable for a building and training Machine Learning models. In other words, whenever the data is gathered from different sources it is collected in raw format which is not feasible for the analysis. Data pre-processing is an integral step in Machine Learning as the quality of data and the useful information that can be derived from it directly affects the ability of our model to learn; therefore, it is extremely important that we pre-process our data before feeding it into our model

Dropping unnecessary columns from datasets

```

In [8]: df_train.drop('Id',axis=1,inplace=True) # id column not necessary for prediction
df_train.drop('Utilities',axis=1,inplace=True) # contains same value in every row
df_train.drop('PoolArea',axis=1,inplace=True) # contains same value in every row
df_train.drop('PoolQC',axis=1,inplace=True) # contains same value in every row
df_test.drop('Id',axis=1,inplace=True) # id column not necessary for prediction
df_test.drop('Utilities',axis=1,inplace=True) # id column not necessary for prediction
df_test.drop('PoolArea',axis=1,inplace=True) # id column not necessary for prediction
df_test.drop('PoolQC',axis=1,inplace=True) #contains same value in every row

```

Handling the missing values in datasets

```

In [9]: #checking for null values
df_train.isnull().sum(),df_test.isnull().sum()

Data Inputs- Logic - Output Relationships

The given dataset has 77 columns after pre processing of the data in which the “SalesPrice” column is an output column. The below analysis describes the relationship behind the data input, its format, the logic in between and the output.

Replacing the Categorical values (alphabetic values) to numeric values

```
51]: # encoding all to numeric values

from sklearn.preprocessing import LabelEncoder
le=LabelEncoder()
list1=['MSZoning','Street','Alley', 'LotShape','LandContour','LotConfig','LandSlope', 'Neighborhood','Condition1','Condition2',

Summary Statistics

In descriptive statistics, summary statistics are used to summarize a set of observations, in order to communicate the largest amount of information as simply as possible. Summary statistics summarize and provide information about your sample data. It tells something about the values in data set. This includes where the average lies and whether the data is skewed.

The `describe()` function computes a summary of statistics pertaining to the Data Frame columns. This function gives the mean, count, max, standard deviation and IQR values of the dataset in a simple understandable way.

Checking correlation in train dataset

Correlation Factor

The statistical relationship between two variables is referred to as their correlation. The correlation factor represents the relation between columns in a given dataset. A correlation can be positive, meaning both variables are moving in the same direction or it can be negative, meaning that when one variable's value increasing, the other variable's value is decreasing.

Checking correlation in train dataset

77 rows x 77 columns

A correlation matrix is a tabular data representing the 'correlations' between pairs of variables in a given dataset. It is also a very important pre-processing step in Machine Learning pipelines. The Correlation matrix is a data analysis representation that is used to summarize data to understand the relationship between various different variables of the given dataset.

```
corr_hmap = df_train.corr()
plt.figure(figsize=(30,30))
sns.heatmap(corr_hmap,annot=True)
plt.show()
```

The figure displays a heatmap of the correlation matrix for 68 variables. The x-axis and y-axis labels include: Age, BMI, Blood Pressure, Cholesterol, Diabetes, Glucose, HDL, Height, Hypertension, LDL, Lipid Levels, Male, Married, Nausea or Vomiting, Number of Children, Number of Pregnancies, Preeclampsia, Race, Smoking Status, Spontaneous Abortion, Stillborn, Total Cholesterol, Uterine Fibroids, Vascular Disease, Weight Gain During Pregnancy, and Years Since Last Menstrual Period. The color intensity indicates the strength and direction of the correlation, with a color bar on the right ranging from -0.9 (dark blue) to 0.9 (light yellow).

Skewness

Skewness refers to distortion or asymmetry in a symmetrical bell curve, or normal distribution in a set of data. Besides positive and negative skew, distributions can also be said to have zero or undefined skew. The skewness value can be positive, zero, negative, or undefined.

Check skewness in datasets.

For test dataset

```
In [121]: df_test.hist(figsize=(30,30));
```

Checking skewness

```

Treating Skewness

In the Data Science it is just statistics and many algorithms revolve around the assumption that the data is normalized. So, the more the data is close to normal, the better it is for getting good predictions. There are many ways of transforming skewed data such as log transform, square-root transform, box-cox transform, etc.

1. Log Transform

Log transformation is a data transformation method in which it replaces each variable x with a $\log(x)$. The log transformation is, arguably, the most popular among the different types of transformations used to transform skewed data to approximately conform to normality

2. Square Root Transform

The square root, x to $x^{(1/2)} = \text{sqrt}(x)$, is a transformation with a moderate effect on distribution shape: it is weaker than the logarithm and the cube root. It is also used for reducing right skewness, and also has the advantage that it can be applied to zero values. So applying a square root transform inflates smaller numbers but stabilises bigger ones.

3. Box-Cox Transform

In statistics, a power transform is a family of functions that are applied to create a monotonic transformation of data using power functions. This is a useful data transformation technique used to stabilize variance, make the data more normal distribution-like, improve the validity of measures of association such as the Pearson correlation between variables and for other data stabilization procedures.

```
In [63]: # Treating the skewness for train dataset
df_x.skew()
for col in df_x.skew().index:
    if col in df_x.describe().columns:
        if df_x[col].skew() > 0.55:
            df_x[col] = np.sqrt(df_x[col])
        if df_x[col].skew() < -0.55:
            df_x[col] = np.cbrt(df_x[col])
```

```
]: # Treating the skewness
df_test.skew()
for col in df_test.skew().index:
    if col in df_test.describe().columns:
        if df_test[col].skew() > 0.55:
            df_test[col] = np.sqrt(df_test[col])
        if df_test[col].skew() < -0.55:
            df_test[col] = np.cbrt(df_test[col])
```

Outliers

An outlier is a data point in a data set which is distant or far from all other observations available. It is a data point which lies outside the overall distribution which is available in the dataset. In statistics, an outlier is an observation point that is distant from other observations.

A box plot is a method or a process for graphically representing groups of numerical data through their quartiles. Outliers may also be plotted as an individual point. If there is an outlier it will be plotted as a point in a box plot but other numerical data will be grouped together and displayed as boxes in the diagram. In most cases a threshold of 3 or -3 is used i.e. if the Z-score value is higher than or less than 3 or -3 respectively, that particular data point will be identified as an outlier.

Plotting outliers in the Dataset

For Train Dataset

```
In [57]: collist=df_train.columns.values
ncol=7
nrow=11

plt.figure(figsize=(25, 75))
plt.rcParams.update({'font.size': 10})
for i in range(0, len(collist)):
    plt.subplot(nrow, ncol, i+1)
    sns.boxplot(df_train[collist[i]], orient='v')
plt.tight_layout()
```

For Test Dataset

```
In [58]: collist=df_test.columns.values
ncol=7
nrow=11

plt.figure(figsize=(25, 50))
plt.rcParams.update({'font.size': 10})
for i in range(0, len(collist)):
    plt.subplot(nrow, ncol, i+1)
    sns.boxplot(df_test[collist[i]], orient='v')
plt.tight_layout()
```

Hardware and Software Requirements and Tools Used

1. Software Tools used

Python 3.0

MS – Office

Operating System - Windows 10

2. Minimum Hardware Requirement

Processors: Intel Atom® processor or Intel® Core™ i3 processor

Disk space: 2 GB – 3 GB

Operating systems: Windows* 7 or later, macOS, and Linux

Python* versions: 2.7.X, 3.6.X

Model/s Development and Evaluation

Identification of possible problem-solving approaches (methods)

From the given dataset it can be concluded that it is a Regression problem as the output column “SalesPrice” has continuous output. So for further analysis of the problem we have to import or call out the Regression related libraries in Python work frame.

The different libraries used for the problem solving are

sklearn - Scikit-learn is a free machine learning library for Python. It features various algorithms like support vector machine, random forests, and k-neighbours, and it also supports Python numerical and scientific libraries like NumPy and SciPy.

1. **sklearn.linear_model**

- i. **Linear Regression** - Linear regression - is a linear model, e.g. a model that assumes a linear relationship between the input variables (x) and the single output variable (y). More specifically, that y can be calculated from a linear combination of the input variables (x). In statistics, linear regression is a linear approach to modelling the relationship between a scalar response and one or more explanatory variables. The case of one explanatory variable is called simple linear regression; for more than one, the process is called multiple linear regressions.
- ii. **Lasso** - In statistics and machine learning, lasso is a regression analysis method that performs both variable selection and

regularization in order to enhance the prediction accuracy and interpretability of the resulting statistical model

Lasso regression is a type of linear regression that uses shrinkage. Shrinkage is where data values are shrunk towards a central point, like the mean. The lasso procedure encourages simple, sparse models (i.e. models with fewer parameters). This particular type of regression is well-suited for models showing high levels of multicollinearity or when you want to automate certain parts of model selection, like variable selection/parameter elimination.

iii. Ridge - The regression is a way to create a parsimonious model when the number of predictor variables in a set exceeds the number of observations, or when a data set has multicollinearity (correlations between predictor variables). Ridge regression is particularly useful to mitigate the problem of multicollinearity in linear regression, which commonly occurs in models with large numbers of parameters. In general, the method provides improved efficiency in parameter estimation problems in exchange for a tolerable amount of bias.

iv. Elastic Net - It is a popular type of regularized linear regression that combines two popular penalties, specifically the L1 and L2 penalty functions. Elastic net linear regression uses the penalties from both the lasso and ridge techniques to regularize regression models. The technique combines both the lasso and ridge regression methods by learning from their shortcomings to improve on the regularization of statistical models.

The elastic net method improves on lasso's limitations, i.e., where lasso takes a few samples for high dimensional data, the elastic net procedure provides the inclusion of "n" number of variables until saturation. In a case where the variables are highly correlated groups, lasso tends to choose one variable from such groups and ignore the rest entirely.

To eliminate the limitations found in lasso, the elastic net includes a quadratic expression ($||\beta||^2$) in the penalty, which, when used in

isolation, becomes ridge regression. The quadratic expression in the penalty elevates the loss function toward being convex. The elastic net draws on best of both i.e., lasso and ridge regression. In the procedure for finding the elastic net method's estimator, there are two stages that involve both the lasso and regression techniques. It first finds the ridge regression coefficients and then conducts the second step by using a lasso sort of shrinkage of the coefficients.

2. **sklearn.tree** –

Decision Trees (DTs) are a non-parametric supervised learning method used for classification and regression. The goal is to create a model that predicts the value of a target variable by learning simple decision rules inferred from the data features. There are several advantages of using decision trees for predictive analysis:

1. Decision trees can be used to predict both continuous and discrete values i.e. they work well for both regression and classification tasks.
2. They require relatively less effort for training the algorithm.
3. They can be used to classify non-linearly separable data.
4. They're very fast and efficient compared to KNN and other algorithms.

Decision tree learning is one of the predictive modeling approaches used in statistics, data mining and machine learning. It uses a decision tree to go from observations about an item to conclusions about the item's target value.

Decision Tree Regressor - Decision Tree is one of the most commonly used, practical approaches for supervised learning. It can be used to solve both Regression and Classification tasks with the latter being put more into practical application. It is a tree-structured classifier with three types of nodes.

Decision tree builds regression or classification models in the form of a tree structure. It breaks down a dataset into smaller and smaller subsets while at the same time an associated decision tree is incrementally developed. The final result is a tree with decision nodes and leaf nodes. A decision node (e.g., Outlook) has two or more branches (e.g., Sunny, Overcast and Rainy), each representing values for the attribute tested. Leaf node (e.g., Hours Played) represents a decision on

the numerical target. The topmost decision node in a tree which corresponds to the best predictor called root node. Decision trees can handle both categorical and numerical data.

3. **sklearn.ensemble**

The goal of ensemble methods is to combine the predictions of several base estimators built with a given learning algorithm in order to improve generalizability / robustness over a single estimator. The sklearn.ensemble module includes two averaging algorithms based on randomized decision trees: the RandomForest algorithm and the Extra-Trees method. Both algorithms are perturb-and-combine techniques specifically designed for trees. This means a diverse set of classifiers is created by introducing randomness in the classifier construction. The prediction of the ensemble is given as the averaged prediction of the individual classifiers.

Boosting ensemble algorithms creates a sequence of models that attempt to correct the mistakes of the models before them in the sequence. Once created, the models make predictions which may be weighted by their demonstrated accuracy and the results are combined to create a final output prediction.

The different types of ensemble techniques used in the model are

- i. **Random Forest Regressor** - It is a meta estimator that fits a number of classifying decision trees on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. A Random Forest's nonlinear nature can give it a leg up over linear algorithms, making it a great option. Random forest is a type of supervised learning algorithm that uses ensemble methods (bagging) to solve both regression and classification problems. The algorithm operates by constructing a multitude of decision trees at training time and outputting the mean/mode of prediction of the individual trees.

- ii. **AdaBoost Regressor** - It is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.
- 4. **sklearn.metrics** - The sklearn. metrics module implements several loss, score, and utility functions to measure classification performance. Some metrics might require probability estimates of the positive class, confidence values, or binary decisions values.

Important sklearn.metrics modules used in the project are

- i. **mean_absolute_error** - In statistics, mean absolute error is a measure of errors between paired observations expressing the same phenomenon. Examples of Y versus X include comparisons of predicted versus observed, subsequent time versus initial time, and one technique of measurement versus an alternative technique of measurement. The MAE measures the average magnitude of the errors in a set of forecasts, without considering their direction. It measures accuracy for continuous variables. Mean Absolute Error (MAE): MAE measures the average magnitude of the errors in a set of predictions, without considering their direction. It's the average over the test sample of the absolute differences between prediction and actual observation where all individual differences have equal weight.
- ii. **mean_squared_error** - In statistics, the mean squared error or mean squared deviation of an estimator measures the average of the squares of the errors—that is, the average squared difference between the estimated values and the actual value. MSE is a risk function, corresponding to the expected value of the squared error loss. Mean Square Error (MSE) is defined as Mean or Average of the square of the difference between actual and estimated values.
- iii. **r2_score** - In statistics, the coefficient of determination, denoted R^2 or r^2 and pronounced "R squared", is the proportion of the variance in the dependent variable that is predictable from the independent variable. R-squared is a statistical measure of how close the data are to the fitted

regression line. It is also known as the coefficient of determination, or the coefficient of multiple determinations for multiple regressions.

5. **sklearn.model_selection** –

- i. **GridSearchCV** - It is a library function that is a member of sklearn's model_selection package. It helps to loop through predefined hyper parameters and fit your estimator (model) on your training set. So, in the end, you can select the best parameters from the listed hyperparameters. GridSearchCV combines an estimator with a grid search preamble to tune hyper-parameters. The method picks the optimal parameter from the grid search and uses it with the estimator selected by the user.
- ii. **. cross_val_score** - Cross validation helps to find out the over fitting and under fitting of the model. In the cross validation the model is made to run on different subsets of the dataset which will get multiple measures of the model. If we take 5 folds, the data will be divided into 5 pieces where each part being 20% of full dataset. While running the Cross validation the 1st part (20%) of the 5 parts will be kept out as a hold out set for validation and everything else is used for training data. This way we will get the first estimate of the model quality of the dataset. In the similar way further iterations are made for the second 20% of the dataset is held as a hold out set and remaining 4 parts are used for training data during process. This way we will get the second estimate of the model quality of the dataset. These steps are repeated during the cross validation process to get the remaining estimate of the model quality.
cross_val_score estimates the expected accuracy of the model on out-of-training data (pulled from the same underlying process as the training data). The benefit is that one need not set aside any data to obtain this metric, and we can still train the model on all of the available data.

Testing of Identified Approaches (Algorithms)

Algorithm used for training and testing.

After completing the required pre processing techniques for the model building data is separated as input and output columns before passing it to the train_test_split.

```
In [62]: #splitting the data for training and test
df_x=df_train.drop(columns=['SalePrice'])
y=df_train['SalePrice']
```

Scaling the input variables

StandardScaler - For each value in a feature, StandardScaler subtracts the minimum value in the feature and then divides by the range. The range is the difference between the original maximum and original minimum. StandardScaler preserves the shape of the original distribution.

For Train Dataset

```
|: from sklearn.preprocessing import StandardScaler
scale=StandardScaler()
x=scale.fit_transform(df_x)
```

For Test Dataset

```
|: from sklearn.preprocessing import StandardScaler
scale=StandardScaler()
df_test=scale.fit_transform(df_test)
```

Applying PCA

An important machine learning method for dimensionality reduction is called Principal Component Analysis. It is a method that uses simple matrix operations from linear algebra and statistics to calculate a projection of the original data into the same number or fewer dimensions.

For Train Dataset

```
0]: from sklearn.decomposition import PCA
pca = PCA(n_components=10)
x=pca.fit_transform(x)
```

For Test Dataset

```
1]: from sklearn.decomposition import PCA
pca = PCA(n_components=10)
df_test=pca.fit_transform(df_test)
```

Splitting the data into training and testing data

Train Test Split

Scikit-learn is a Python library that offers various features for data processing that can be used for classification, clustering, and model selection. Model_selection is a method for setting a blueprint to analyze data and then using it to measure new data. Selecting a proper model allows you to generate accurate results when making a prediction. If we have one dataset, then it needs to be split by using the Sklearn train_test_split function first. By default, Sklearn train_test_split will make random partitions for the two subsets.

The train_test_split is a function in Sklearn model selection for splitting data arrays into two subsets: for training data and for testing data. With this function, we don't need to divide the dataset manually. The train_test_split function is for splitting a single dataset for two different purposes: training and testing. The training subset is for building your model. The testing subset is for using the model on unknown data to evaluate the performance of the model.

```
#Splitting the data into training and testing data

from sklearn.model_selection import train_test_split
x_train, x_test, y_train, y_test=train_test_split(x, y, test_size=.20, random_state=42)
```

Run and Evaluate selected models

Before running the model & evaluating them, first we need to import all the necessary libraries which are required for the problem solving.

```
[72]: from sklearn.metrics import accuracy_score
      from sklearn.model_selection import train_test_split
      from sklearn.metrics import mean_squared_error,mean_absolute_error
      from sklearn.metrics import r2_score

[73]: x_train,x_test,y_train,y_test=train_test_split(x,y,test_size=.22,random_state=42)

[74]: from sklearn.linear_model import LinearRegression,Lasso,Ridge,ElasticNet
      from sklearn.tree import DecisionTreeRegressor
      from sklearn.neighbors import KNeighborsRegressor
```

Now using for loop running all the models such as “Linear Regression, Lasso, Ridge, ElasticNet, KNeighborsRegressor, Decision Tree Regressor.

```
In [76]: x_train,x_test,y_train,y_test=train_test_split(x,y,test_size=.22,random_state=49)
model=[LinearRegression(),Lasso(),Ridge(),ElasticNet(),DecisionTreeRegressor(),KNeighborsRegressor()]

for m in model:
    m.fit(x_train,y_train)
    print("Results of ",m," is")
    predm=m.predict(x_test)
    print("R2 Score:",r2_score(y_test,predm))
    print("Error:")
    print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,predm)))
    print("*****")
    print('\n')
```

Output

Key Metrics for success in solving problem under consideration

As the Lasso, Ridge, Gradientboosting & Random Forest Regressor models are giving best results on the dataset further we can find out the best parameters of these models using GridSearchCV. Using these best params we will be able to improve the overall score & accuracy of the models.

Using GridSearchCV to find out the best parameter in Lasso Regression

```
81]: from sklearn.model_selection import GridSearchCV

82]: #Lasso model is giving the best score so finding its best parameter using GridSearchCV

lasso=Lasso()
parameters={"alpha" :[0.001, 0.01, 0.1, 1], 'random_state':range(42, 100)}
clf = GridSearchCV(lasso, parameters)
clf.fit(x, y)
clf.best_params_

82]: {'alpha': 1, 'random_state': 42}

83]: # Lasso model
lasso=Lasso(alpha= 1, random_state= 42)
lasso.fit(x_train,y_train)
pred=lasso.predict(x_test)
print("R2 Score:",r2_score(y_test,pred))
print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,pred)))

R2 Score: 0.8663870135280889
Root Mean Squared Error: 28578.132295844167
```

Using GridSearchCV to find out the best parameter in Ridge Regression

```
1]: #Ridge model is giving the GOOD score so finding its best parameter using GridSearchCV

ridge=Ridge()
parameters={"alpha" :[0.001, 0.01, 0.1, 1], 'random_state':range(42, 100)}
clf = GridSearchCV(ridge, parameters)
clf.fit(x_train, y_train)
clf.best_params_

1]: {'alpha': 1, 'random_state': 42}

2]: # APPLYING TO RIDGE ITS BEST PARAMETERS
ridge=Ridge(alpha= 1, random_state= 42)
ridge.fit(x_train,y_train)
pred=ridge.predict(x_test)
print("R2 Score:",r2_score(y_test,pred))
print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,pred)))

R2 Score: 0.8663870717978961
Root Mean Squared Error: 28578.126064255146
```

Using GridSearchCV to find out the best parameter in Random Forest Regressor

```
[88]: rfr=RandomForestRegressor()
      parameters={'n_estimators':[50,100,150,200]}
      clf=GridSearchCV(rfr,parameters)
      clf.fit(x_train,y_train)
      clf.best_params_

[88]: {'n_estimators': 50}

[89]: rfr=RandomForestRegressor(n_estimators=50)
      rfr.fit(x_train,y_train)
      predrfr=rfr.predict(x_test)
      print("R2 Score:",r2_score(y_test,predrfr))
      print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,predrfr)))

      R2 Score: 0.8541875236889113
      Root Mean Squared Error: 29854.297034451127
```

Using GridSearchCV to find out the best parameter in Gradient Boosting Regressor

```
5]: gbr=GradientBoostingRegressor()
     estimator={'n_estimators':[100,200,300]}
     clf=GridSearchCV(gbr,estimator)
     clf.fit(x_train,y_train)
     clf.best_params_

5]: {'n_estimators': 100}

7]: gbr=GradientBoostingRegressor(n_estimators=100)
     gbr.fit(x_train,y_train)
     predgbr=gbr.predict(x_test)
     print("R2 Score:",r2_score(y_test,predgbr))
     print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,predgbr)))

      R2 Score: 0.8738522309889252
      Root Mean Squared Error: 27768.30007299185
```

Choosing the best Model

```
gbr=GradientBoostingRegressor(n_estimators=100)
gbr.fit(x_train,y_train)
predgbr=gbr.predict(x_test)
print("R2 Score:",r2_score(y_test,predgbr))
print("Root Mean Squared Error:",np.sqrt(mean_squared_error(y_test,predgbr)))

      R2 Score: 0.8738522309889252
      Root Mean Squared Error: 27768.30007299185
```

```
#cross validation

from sklearn.model_selection import cross_val_score

scores=cross_val_score(gbr,x,y,cv=5)

```

Visualizations & Interpretation of the Results

Now we can analyze all the plots, graphs in the dataset and the inferences and observations obtained from them.

Univariate Analysis

Checking the distribution of Target column

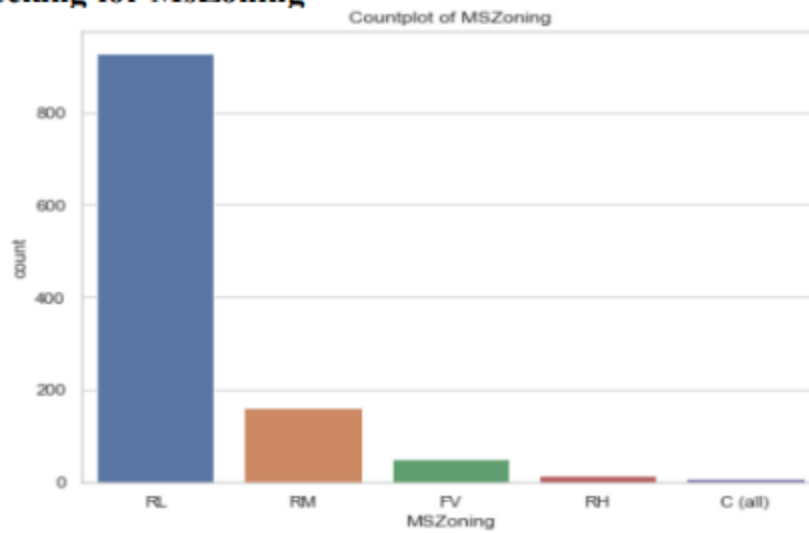

```
140000    18
135000    16
155000    12
139000    11
160000    11
..
126175     1
204000     1
186000     1
369900     1
105500     1
Name: SalePrice, Length: 581, dtype: int64
```

Observation:

Maximum number of SalePrice lies between 140000 and 230000.

Checking for MsZoning

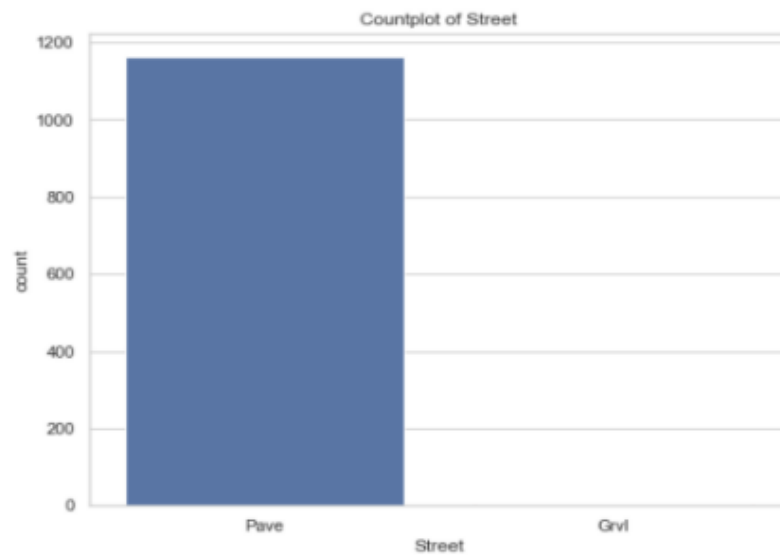

```
8]: RL      928
    RM      163
    FV       52
    RH       16
    C (all)    9
    Name: MSZoning, dtype: int64
```

Observation:

Maximum, 928 number of MSZoning are RL.

Checking for Street column

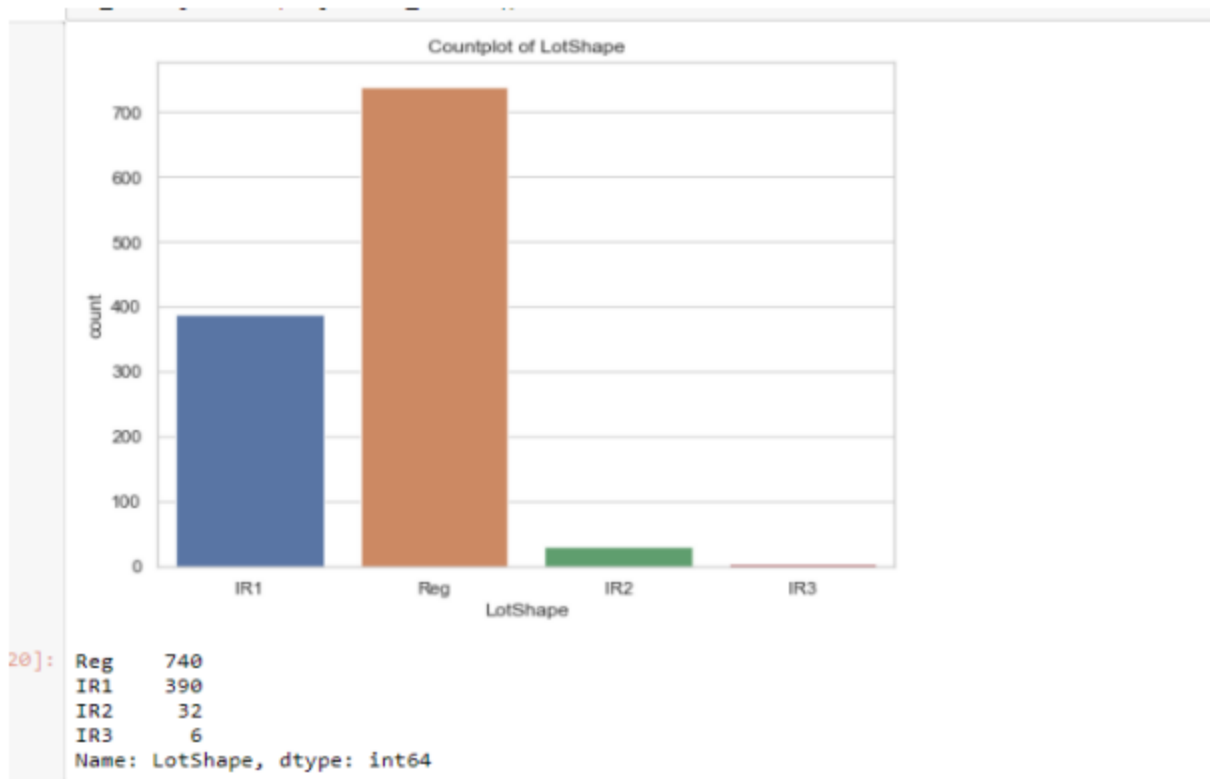

```
] : Pave    1164  
    Grvl     4  
    Name: Street, dtype: int64
```

Observation:

Maximum, 1164 number of Street are Pave where as only 4 are Grvl.

Checking for Lotshape column

Observation:

Maximum, 740 number of LotShape are Reg.

Checking for LandCounter column

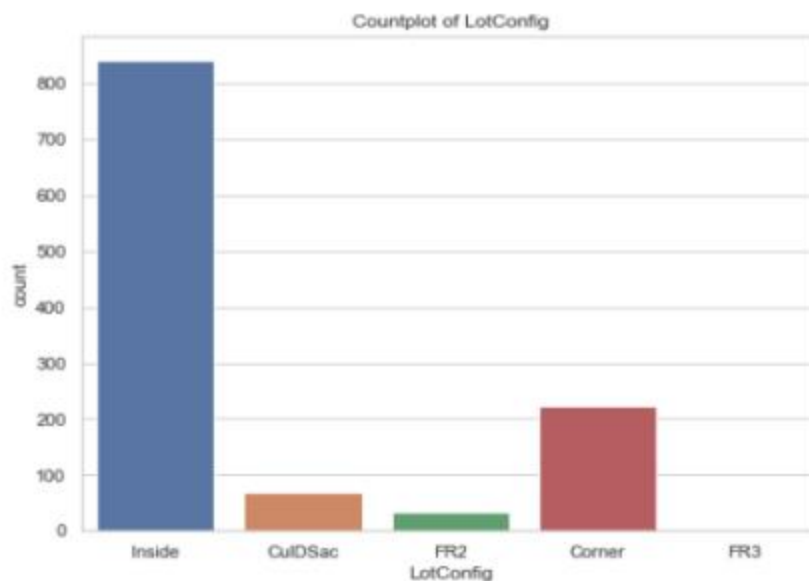

```
21]: Lvl    1046  
     Bnk     50  
     HLS     42  
     Low     30  
     Name: LandContour, dtype: int64
```

Observation:

Maximum, 1046 number of LandContour are Lvl.

Checking for Lotconfig column

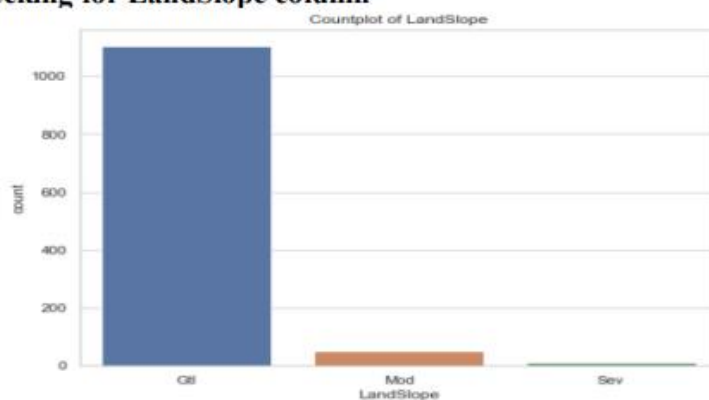

```
22]: Inside      842  
     Corner      222  
     CulDSac      69  
     FR2         33  
     FR3          2  
     Name: LotConfig, dtype: int64
```

Observation:

Maximum, 842 number of LotConfig are Inside.

Checking for LandSlope column

```
3]: Gtl      1105  
     Mod       51  
     Sev       12  
     Name: LandSlope, dtype: int64
```

Observation:

Maximum, 1105 number of LandSlope are Gtl.

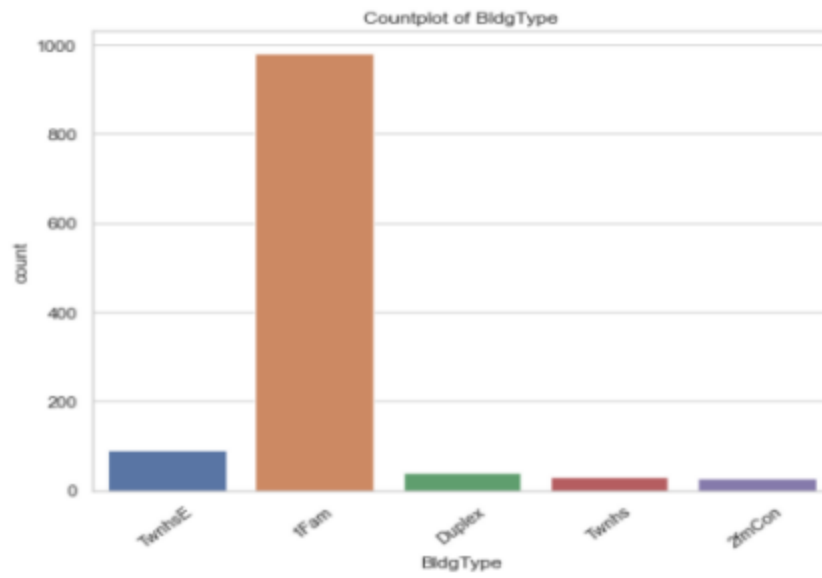

Checking for Condition1 column

```
Norm      1005
Feedr      67
Artery     38
RRAn       20
PosN       17
RRAe        9
PosA        6
RRTnn       4
RRTte       2
Name: Condition1, dtype: int64

Observation:
Maximum, 1005 number of Condition1 is Norm.
```

Checking for Bldgtype column

```
1Fam      981
TwnhseE   90
Duplex    41
Twnhs     29
2fmCon    27
Name: BldgType, dtype: int64
```

Observation:

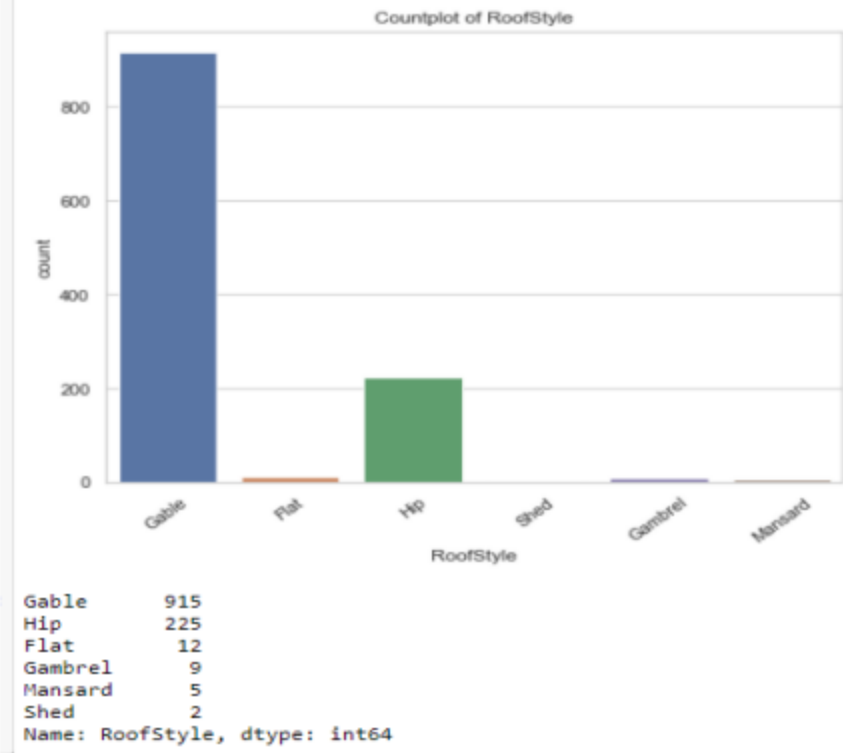

Maximum, 981 number of BldgType are 1Fam.

Checking for HouseStyle column

```
]: 1Story    578
    2Story    361
    1.5Fin    121
    SLvl      47
    SFoyer    32
    1.5Unf    12
    2.5Unf    10
    2.5Fin     7
    Name: HouseStyle, dtype: int64
```

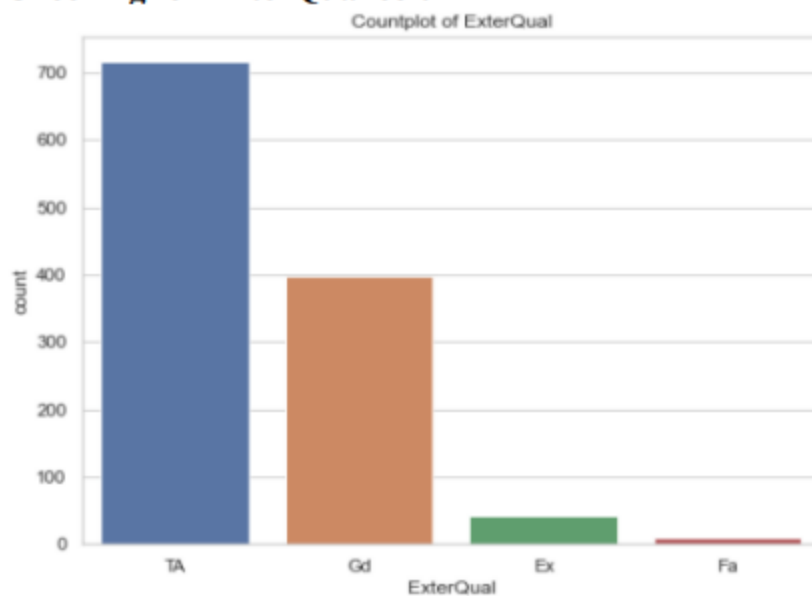

Checking for RoofStyle column

Observation:

Maximum, 915 number of RoofStyle are Gable.

Checking for ExterQual column

```
TA    717
Gd    397
Ex     43
Fa     11
Name: ExterQual, dtype: int64
```

Observation:

Maximum, 717 number of ExterQual is TA.

Checking for Foundation column

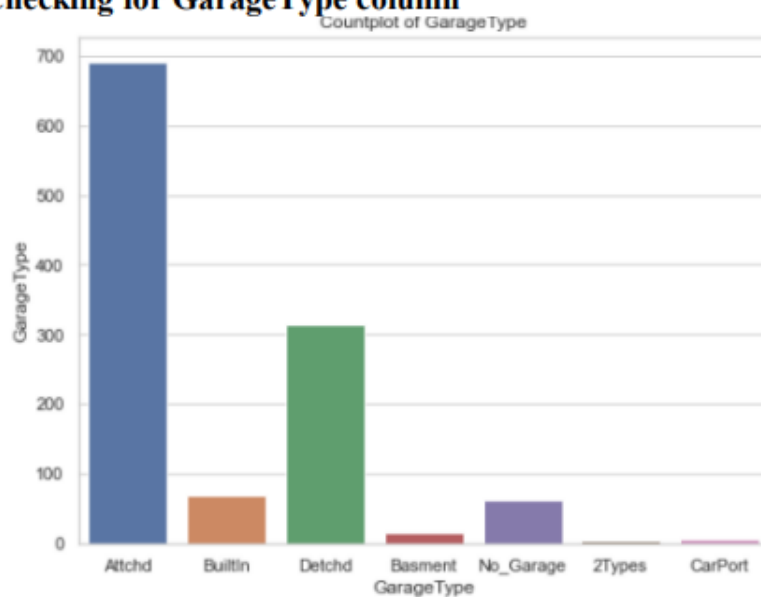

```
0]: CBlock    516  
    PConc    513  
    BrkTil   112  
    Slab     21  
    Stone     5  
    Wood     1  
    Name: Foundation, dtype: int64
```

Observation:

Maximum, 516 number of Foundation are CBlock.

Checking for GarageType column

```
Attchd      691
Detchd      314
BuiltIn       70
No_Garage    64
Basement     16
CarPort       8
2Types        5
Name: GarageType, dtype: int64
```

Observation:

Maximum, 691 number of GarageType are Attchd.

Checking for SaleCondition column

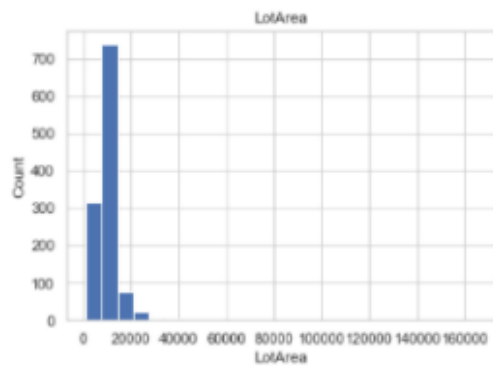

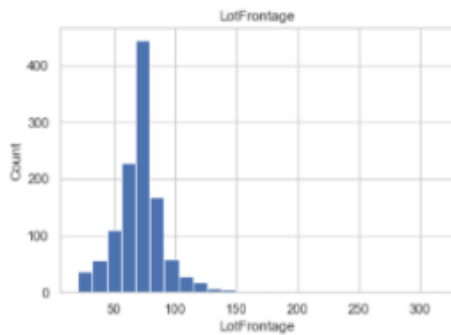

```
3]: Normal      945
   Partial     108
   Abnorml      81
   Family       18
   Alloca       12
   AdjLand        4
   Name: SaleCondition, dtype: int64
```

Observation:

Maximum, 945 number of SaleCondition is normal.

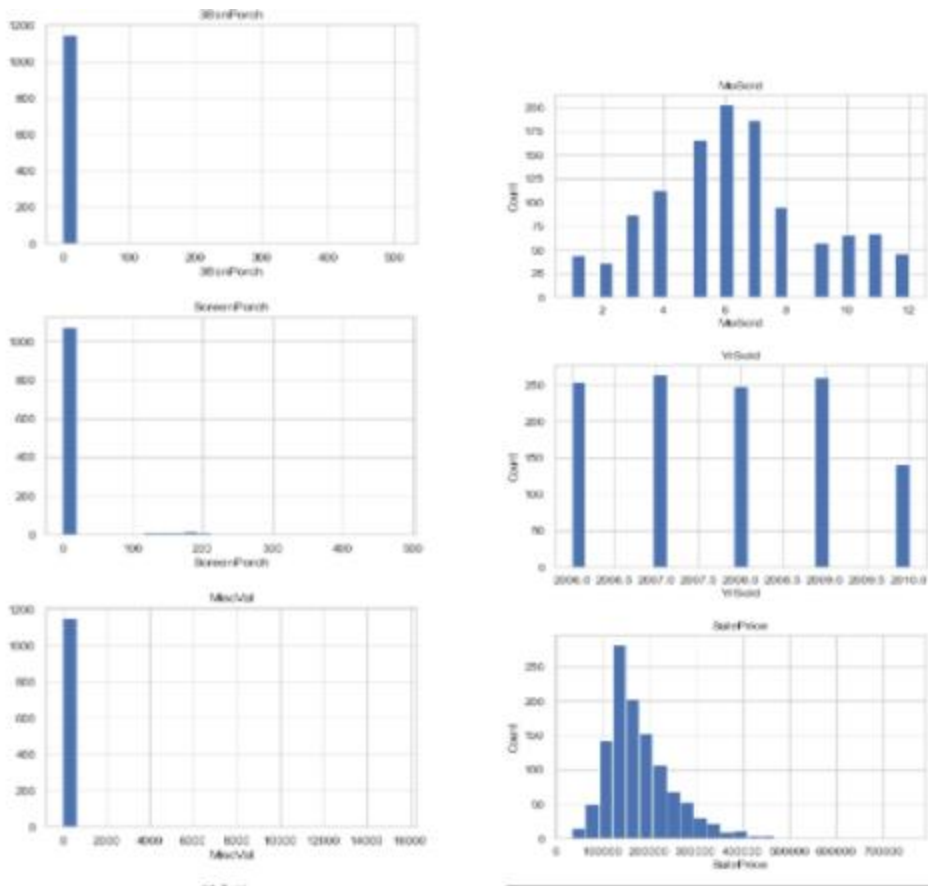

Plotting histogram for numeric column

Bivariate Analysis

Factor plot of MSZoning vs SalePrice

Observation:

SalePrice is maximum with FV MSZoning.

Factor plot of LotShape vs SalePrice

```

SalePrice LotShape
34900      Reg      1
35311      Reg      1
37900      Reg      1
39300      Reg      1
40000      Reg      1
..
582933     Reg      1
611657     IR1      1
625000     IR1      1
745000     IR1      1
755000     IR1      1
Name: LotShape, Length: 733, dtype: int64

```

Observation:

SalePrice is maximum with IR2 LotShape.

Factor plot of LandContour vs SalePrice

```

SalePrice LandContour
34900      Lvl      1
35311      Lvl      1
37900      Lvl      1
39300      Low      1
40000      Lvl      1
..
582933     Lvl      1
611657     Lvl      1
625000     Lvl      1
745000     Lvl      1
755000     Lvl      1
Name: LandContour, Length: 655, dtype: int64

```

Observation:

SalePrice is maximum with HLS LandContour.

Factor plot of LotConfig vs SalePrice

```
SalePrice LotConfig
34900 Inside 1
35311 Inside 1
37900 Inside 1
39300 Inside 1
40000 Inside 1
..
582933 Inside 1
611657 Inside 1
625000 CulDSac 1
745000 Corner 1
755000 Corner 1
Name: LotConfig, Length: 743, dtype: int64
```

Observation:

SalePrice is maximum with CulDsac LotConfig.

Factor plot of Neighbourhood vs SalePrice

```
SalePrice Neighborhood
34900 IDOTRR 1
35311 IDOTRR 1
37900 OldTown 1
39300 BrkSide 1
40000 IDOTRR 1
..
582933 NridgHt 1
611657 NridgHt 1
625000 NoRidge 1
745000 NoRidge 1
755000 NoRidge 1
Name: Neighborhood, Length: 1013, dtype: int64
```

Observation:

SalePrice is maximum with NoRidge Neighborhood.

Factor plot of HouseStyle vs SalePrice

Observation:

SalePrice is maximum with 2.5Fin HouseStyle.

Factor plot of KitchenQual vs SalePrice

Observation:

SalePrice is maximum with Ex PoolQC.

CONCLUSION

- The GradientBoosting Regressor model is working with highest R2 score of 87.385.
- The cross_val_score of model is 83.299359 which again show that cross val score is better compared to other models in the table.
- All these points prove that GradientBoosting Regressor model is working best and can be considered as finalised model.

Learning Outcomes of the Study in respect of Data Science

- 1. Price Prediction modeling** – This allows predicting the prices of houses & how they are varying in nature considering the different factors affecting the prices in the real time scenarios.
- 2. Prediction of Sale Price** – This helps to predict the future revenues based on inputs from the past and different types of factors related to real estate & property related cases. This is best done using predictive data analytics to calculate the future values of houses. This helps in segregating houses, identifying the ones with high future value, and investing more resources on them.
- 3. Deployment of ML models** – The Machine learning models can also predict the houses depending upon the needs of the buyers and recommend them, so customers can make final decisions as per the needs .

Limitations of this work and Scope for Future Work

The biggest limitation I observed was that not all categories of a particular feature were available in the training data. So if there were new category in the test data the model would not be able to identify that.

Example: MSZoning has 8 categories

A Agriculture

C Commercial

FV Floating Village Residential

I Industrial

RH Residential High Density

RL Residential Low Density

RP Residential Low Density Park

RM Residential Medium Density

However in the Training dataset only 5 categories are present ...what happen if other 3 categories will present in test data in future. It would be difficult for machine to identify and predict.
